

"PV Isolation low" troubleshoot guide

The inverter will detect the insulation resistance of the positive & negative input to earth before connecting to grid, if the resistance falls below the setpoint, the inverter will not connect to grid and indicate "PV Isolation low" on LCD display. This is not an inverter fault, the inverter only detects that fault before feeding in, which can appear during initial installation or develop in an existing PV system. If this fault is encountered, you need to check the insulation on DC side.

Possible cause:

- 1. Damaged PV panels or DC wires, such as mounting screw through the back of a module or a conducting wire pinched against a mounting rail;
- 2. Poor connection between PV panels caused by poor quality or aging of cable junction;
- 3. Water ingress or damp condensation in junction box due to not properly sealed junction box or DC isolator enclosure, which will lower the insulation resistance and cause an "PV Isolation low" fault.

General solution:

Check the earth wiring on AC side, check the isolation on DC side(PV side).

1. Check if the inverter is well grounded,

2. Switch off the DC isolator, unplug the DC connectors, then turn on the DC switch to measure the voltage of DC positive to ground and the voltage of DC negative to ground. The reading will be 0 under normal condition, if the voltage is not 0, you can locate the fault area by dividing the voltage by Voc of PV solar module, as in the below example, the Positive to ground voltage is 42V, Negative to ground voltage is 63V, then the fault is located between the 2 and 3 panels.

POS TO NEG = OPEN CIRCUIT VOLTAGE POS TO GND = 0V, NEG TO GND = 0V

GROWATT NEW ENERGY TECHNOLOGY CO., LTD Building B, Jiayu Industrial Zone, #28 Guanghui Road, Longteng Community, Shiyan, Baoan District, Shenzhen, P.R. China

W www.ginverter.com

Where is the Ground Fault? 21 V 21 V 21 V 21 V 21 V 42 / 21 = 2 or 2nd module from the positive home run. 63/21 = 3 or 3rd module from the negative home run. Positive to Negative to Ground Ground 42 Volts 63 Volts

- 3. Then check whether DC wires are pinched between module frames and mounting structures, whether there is mounting screw through the back of a module, conductors rubbing against the roof, mouse chewing on conductors, broken PV modules, incorrect wiring of PV modules.
- 4. Check whether the enclosure of junction box or DC isolator is properly sealed to against water ingress or condensation.

If problem persists after replacing,

The problem can be solved by changing the detecting threshold to a lower value, but there will be a risk of electric shock or fire if the ground fault sustain. Whether to do the change is decided by the customer, Growatt assume no reliability for the risk or consequence of the changing.

Please follow the procedures below to change detect value of grounding resistance.

a. Connect the inverter to your computer via RS232, you can use a USB to RS232 converter cable if your laptop has no RS232 port(9 pins, D type), but make sure the driver for the cable is properly installed. You can check that on Device Manager, if the driver is successfully installed, a USB serial port will be shown under "Ports(COM & LPT), otherwise you will see a yellow exclamation mark or question mark icon.
